### A. The Purpose of Simplified Models

A model of new physics is defined by a TeV-scale effective Lagrangian describing its **particle content and interactions. A simplified model is specifically designed to involve only**

Padhi,<sup>12</sup> Michele Papucci,<sup>13</sup> Michael Park,<sup>4</sup> Myeonghun Park,<sup>14</sup> Maxim Perelstein,<sup>5</sup> Michael Peskin,<sup>1</sup> Daniel Phalen,<sup>8</sup> Keith Behrermann,<sup>15</sup> Vikram Raval,<sup>16</sup> Tuhin Roy,<sup>17</sup>

- **Deriving limits on more general models:** Constraints on a wide variety of models can be deduced from limits on simplified models. Within each final state, simplified model limits can be formulated as an upper limit on the number of events in a signal region, and a parametrized efficiency for each simplified-model topology to populate the signal region. Limits on other models giving rise to the same topologies can

study of experimental efficiencies for a given specific model, as the procedure uses only topologies populated by *both* the specific *and* simplified models. This procedure should therefore **be regarded as an initial check only**, which can be followed by a dedicated study or **RECAST-style analysis [18]** if higher precision is needed.

 4th July 2022

**Measurement of the properties of Higgs boson production at  $\sqrt{s} = 13$  TeV in the  $H \rightarrow \gamma\gamma$  channel using  $139 \text{ fb}^{-1}$  of  $pp$  collision data with the ATLAS experiment**

The ATLAS Collaboration

Measurements of Higgs boson production cross-sections are carried out in the diphoton decay channel using  $139 \text{ fb}^{-1}$  of  $pp$  collision data at  $\sqrt{s} = 13$  TeV collected by the ATLAS experiment at the LHC. The analysis is based on the definition of 101 distinct signal regions using machine-learning techniques. The inclusive Higgs boson signal strength in the diphoton channel is measured to be  $1.04^{+0.10}_{-0.09}$ . Cross-sections for gluon-gluon fusion, vector-boson fusion, associated production with a  $W$  or  $Z$  boson, and top associated production processes are reported. An upper limit of 10 times the Standard Model prediction is set for the associated production process of a Higgs boson with a single top quark, which has a unique sensitivity to the sign of the top quark Yukawa coupling. Higgs boson production is further characterized through measurements of Simplified Template Cross-Sections (STXS). In total, cross-sections

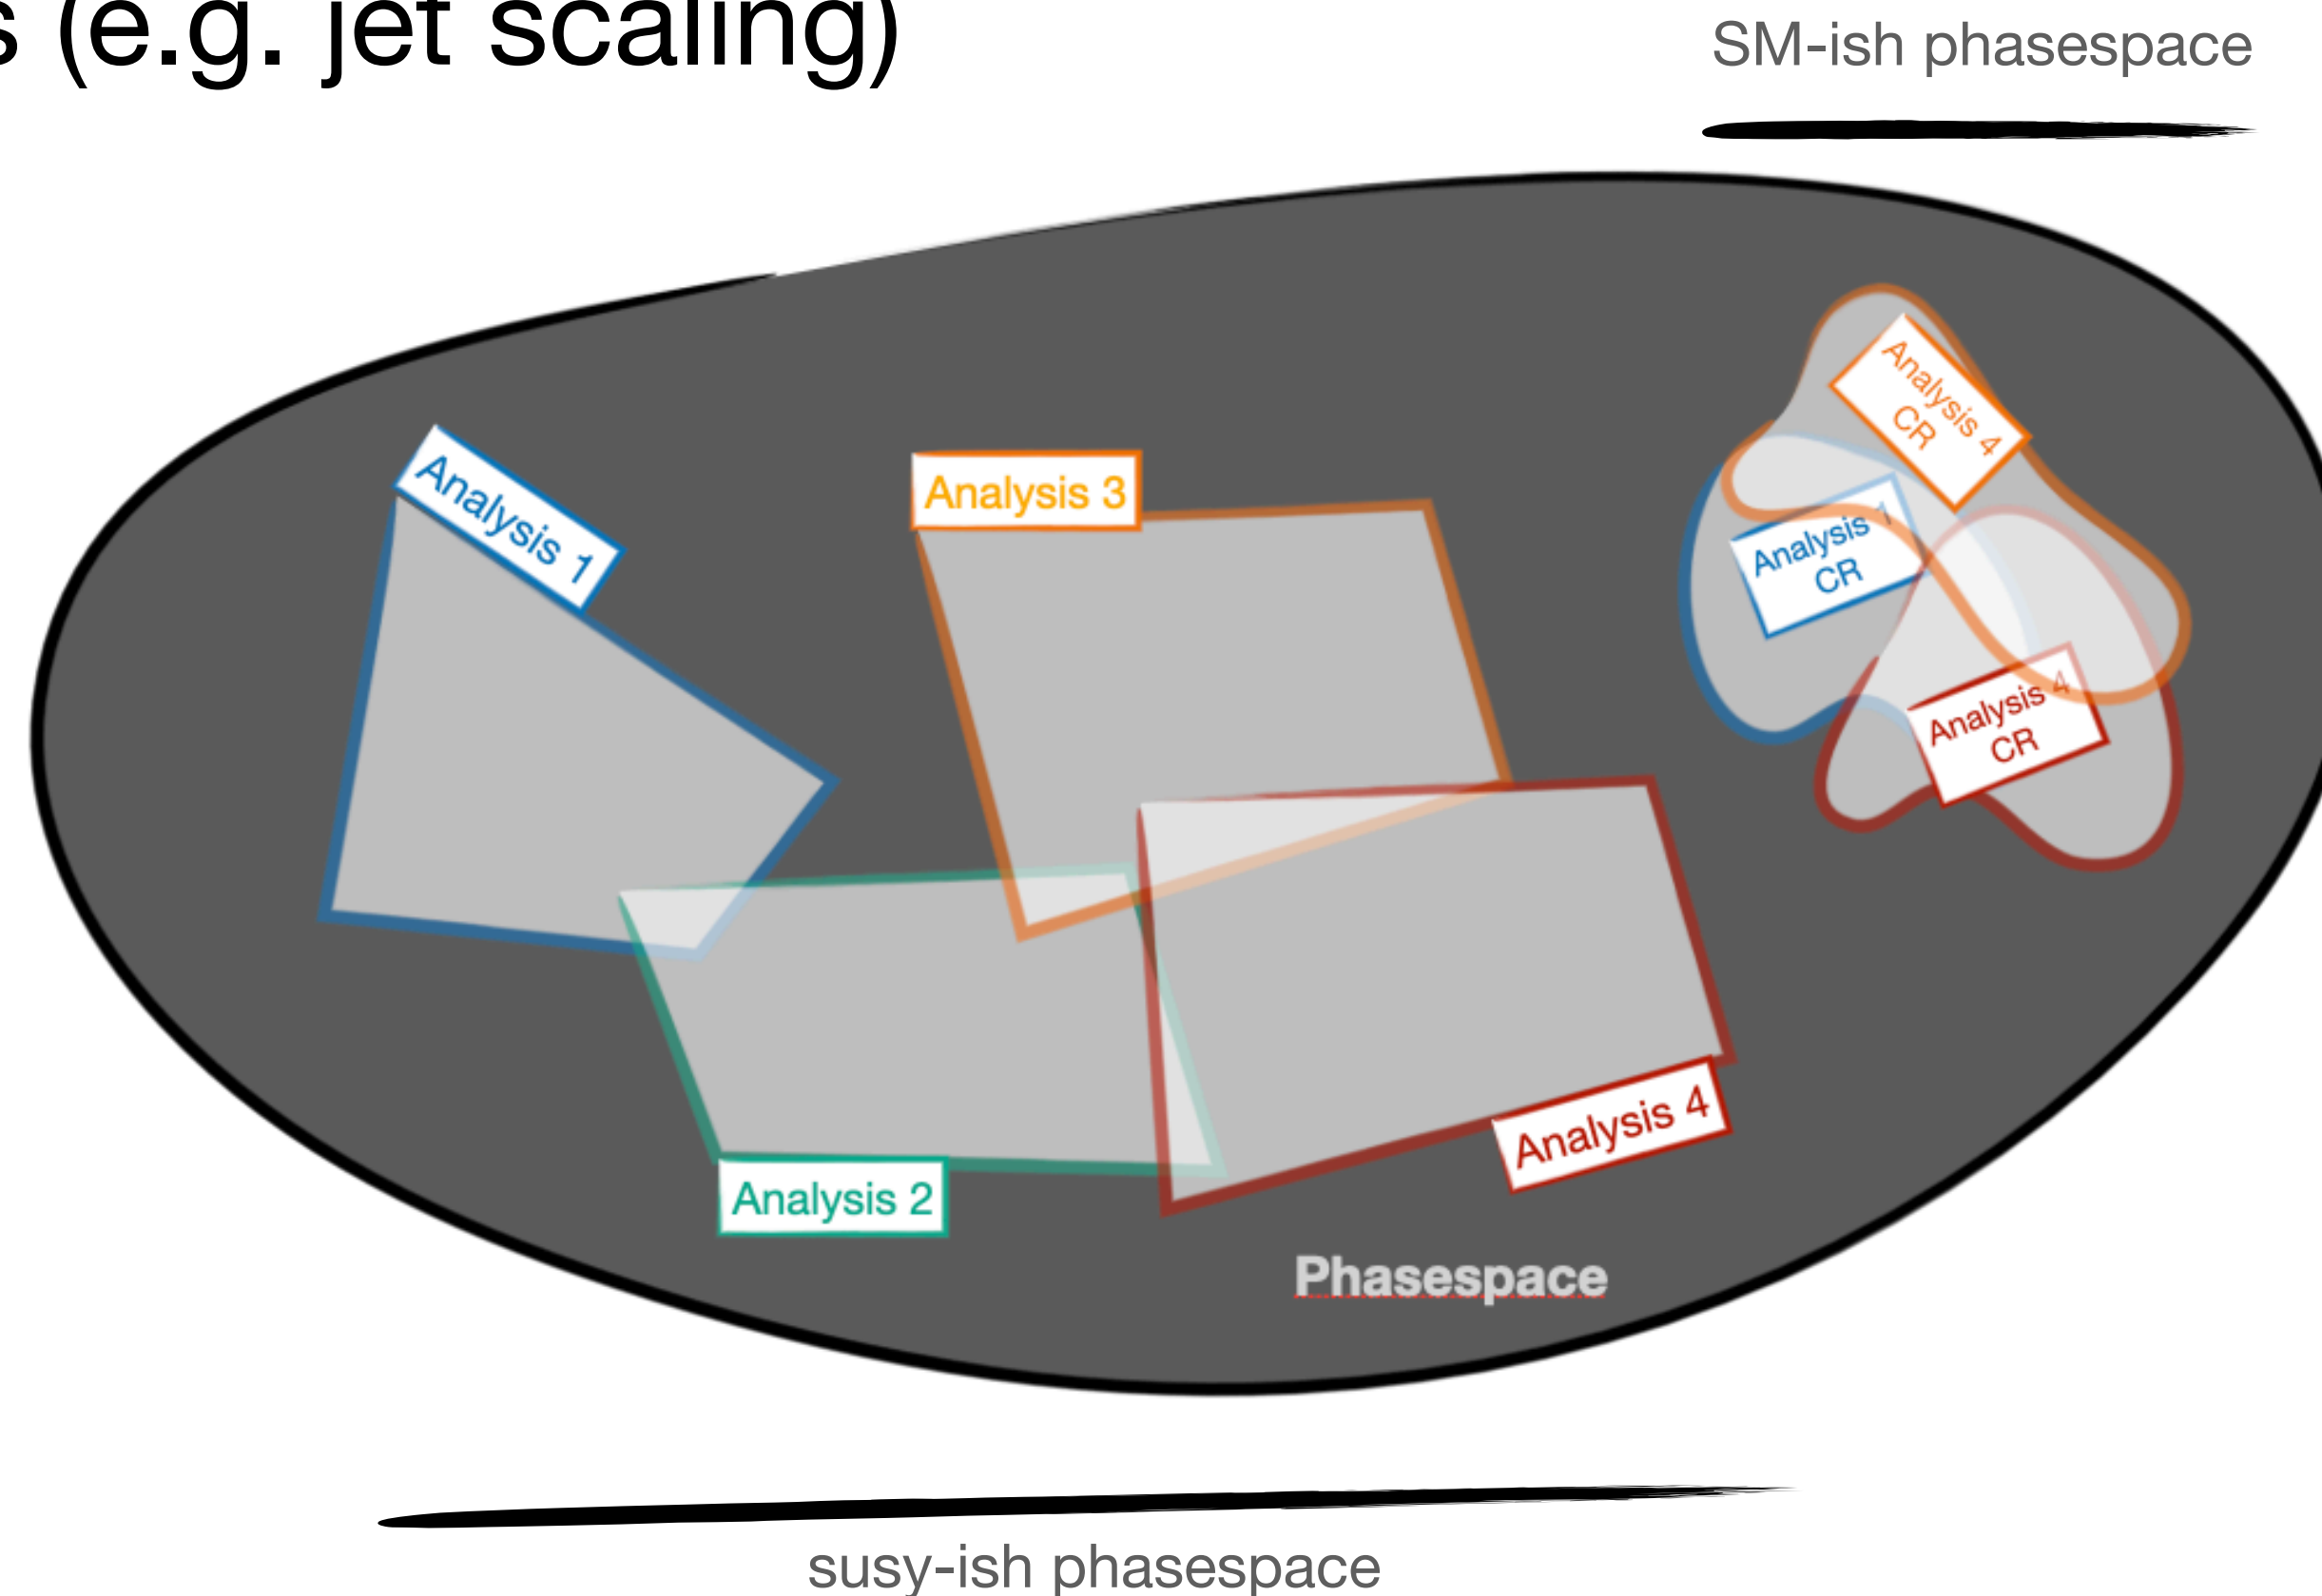

## Experiment

# CR overlap

CRs try to measure SM phasespace, overlap there is probably larger. Those CR might rely on certain “inclusiveness” to provide enough stats to have simpler marginal distributions (e.g. jet scaling)

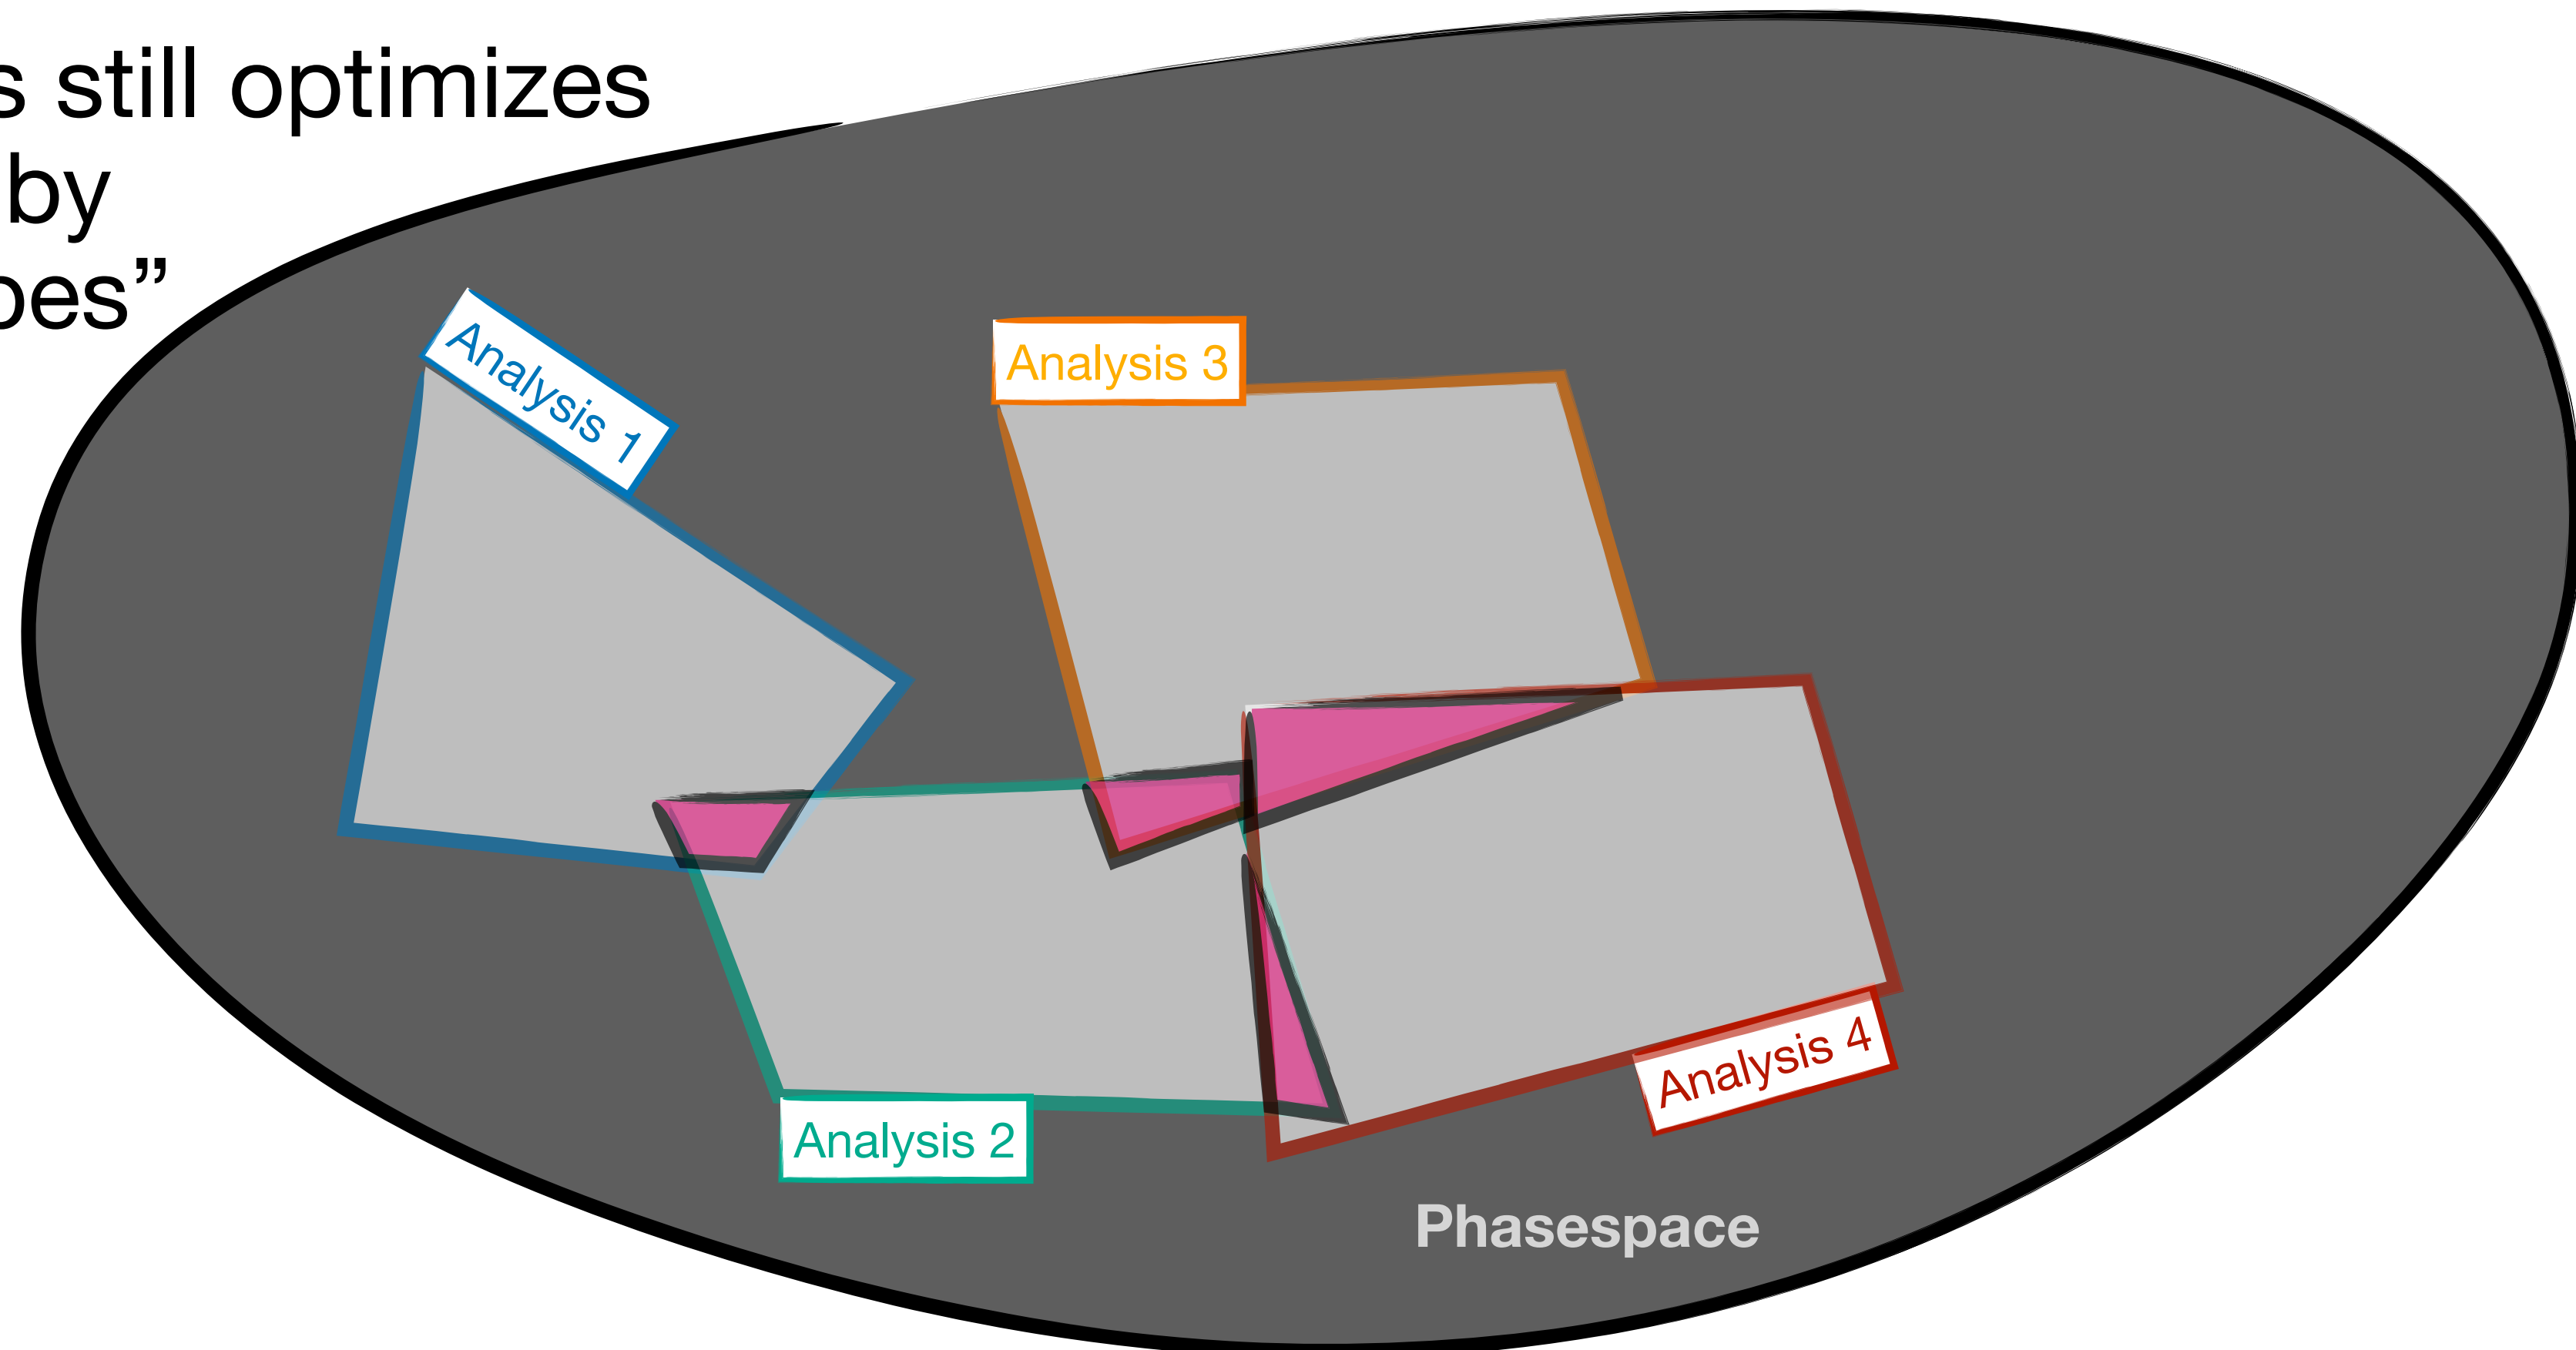

Difficult problem.

# Phasespace-“data cubes”

At a coarse level, coordinate which cuts are admissible to slice up PS in cube internally in a cube could still do neural nets, etc

Each analysis still optimizes for its model by “ordering cubes”

# Phasespace-“data cubes”

At a coarse level, coordinate which cuts are admissible to slice up PS in cube internally in a cube could still do neural nets, etc

Each analysis still optimizes for its model by “ordering cubes”

but combo later on might be easier

**no guessing or MC as to which regions overlap**

# Phasespace-“data cubes”

At a coarse level, coordinate which cuts are admissable to slice up PS in cube internally in a cube could still do neural nets, etc

Each analysis still optimizes for its model by “ordering cubes”

# Thoughts?

Could we coordinate SUSY Pheno community to produce something akin to STXS that's maps out a "wishlist of phasespaces" to be measured?

Reinterpretation Forum seems like the optimal vehicle to drive such a community process

Phrased in a different way:

**Assume ATLAS had capacity for  $N$  recastable analyses ( $N = 50$ ) to do in Run-X of the LHC. what would be the optimal subset of phasespace one should measure**
