

# Measurement of the 1-jettiness Event Shape Observable in Deep-inelastic Electron-Proton Scattering

J. Hessler for the H1 collaboration

31st International Workshop on Deep Inelastic Scattering

Technische Universität München,  
Max-Planck-Institut für Physik

9.4.2024

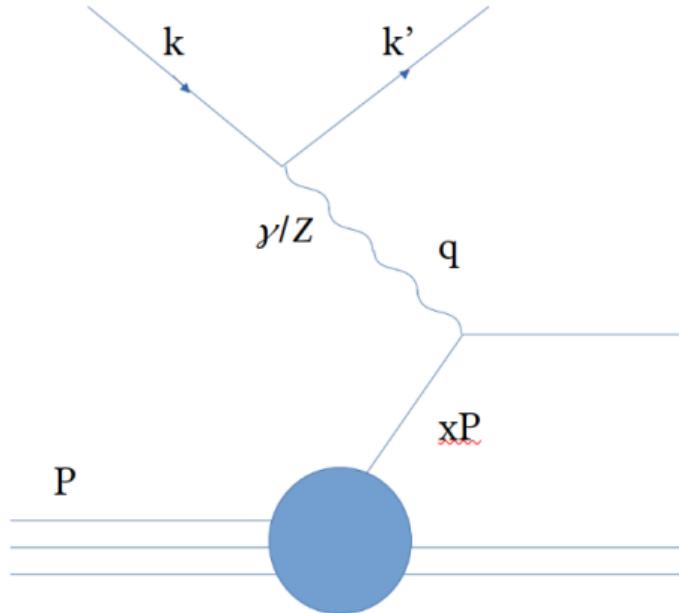

## Neutral current deep-inelastic scattering

- Process  $ep \rightarrow e'X$
- Electron or positron scattering

## Kinematic variables

- Virtuality of exchanged boson  
$$Q^2 = -q^2 = -(k - k')^2$$
- Inelasticity, Bjorken-x and centre-of-mass energy

$$y = \frac{P \cdot q}{P \cdot k} \quad Q^2 = x_{Bj} \cdot y \cdot s$$

# The 1-jettiness event shape observable - Definition

## 1-jettiness $\tau_1^b$

$$\tau_1^b = \frac{2}{Q^2} \sum_{i \in HFS} \min\{xP \cdot p_i, (q + xP) \cdot p_i\}$$

- Axes: Incoming parton and  $(q+xP)$
- Infrared safe and free of non-global logs
- Sensitive to  $\alpha_s$  and parton shower models
- Measurement can be used for MC tuning

## Equivalent expressions

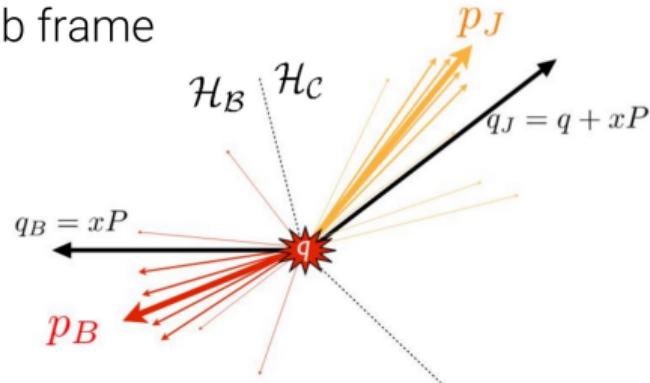

- Using momentum conservation

$$\tau_1^b = 1 - 2 \sum_{i \in HFS} \max\left\{0, \frac{q \cdot p_i}{q \cdot q}\right\}$$

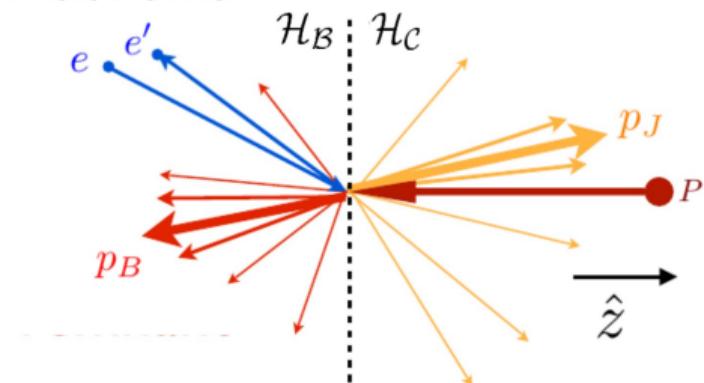

- DIS thrust

$$\tau_1^b = 1 - \frac{2}{Q} \sum_{i \in H_C} P_{z,i}^{Breit}$$

## Lab frame

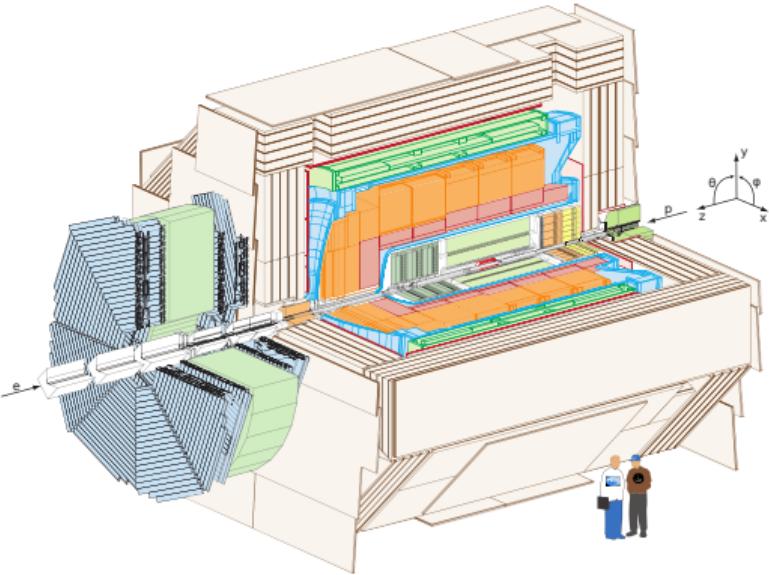

## Breit frame

Kang, Lee, Stewart [Phys.Rev.D 88 (2013) 054004]

# The H1 detector

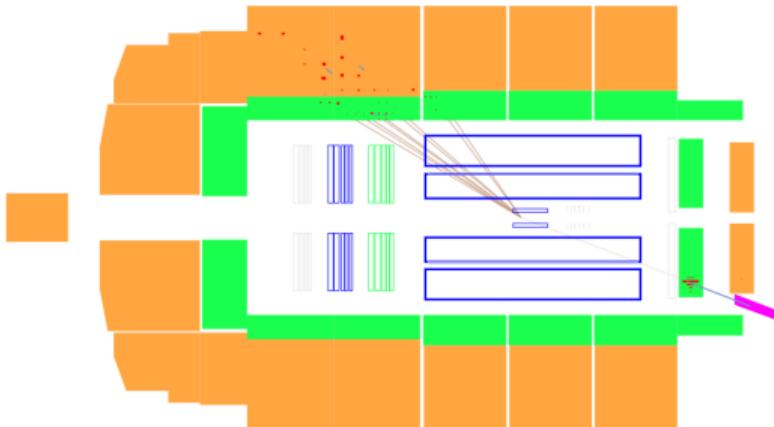

- Data were taken from 2003 to 2007 (HERA-2)
- Electron ( $L = 159.6 \text{ pb}^{-1}$ ) and positron ( $L = 192.0 \text{ pb}^{-1}$ ) runs
- $E_e = 27.6 \text{ GeV}$ ,  $E_p = 920 \text{ GeV}$   
 $\rightarrow \sqrt{s} = 319 \text{ GeV}$
- Asymmetric design with trackers, calorimeter, solenoid, muon-chambers, forward & backward detectors
- Particles are reconstructed using a particle flow algorithm  
 $\rightarrow$  Combining cluster and track information without double-counting of energy

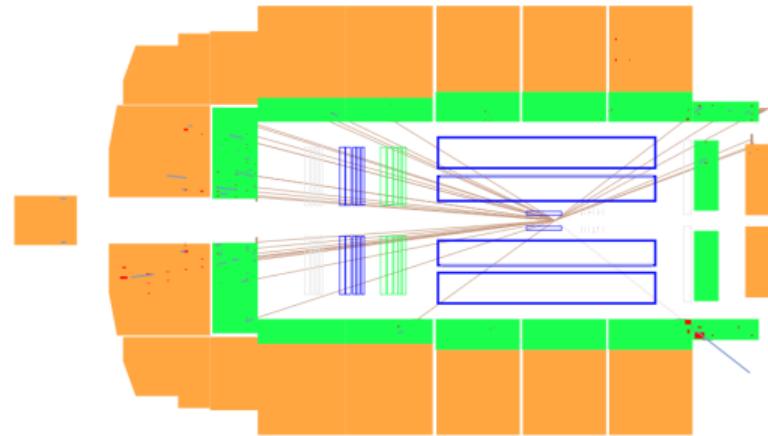

# The 1-jettiness event shape observable - Intuition

**1-jettiness:**  $\tau_1^b = \frac{2}{Q^2} \sum_{i \in HFS} \min\{xP \cdot p_i, (q + xP) \cdot p_i\}$

## Visualisation of the 1-jettiness with event displays

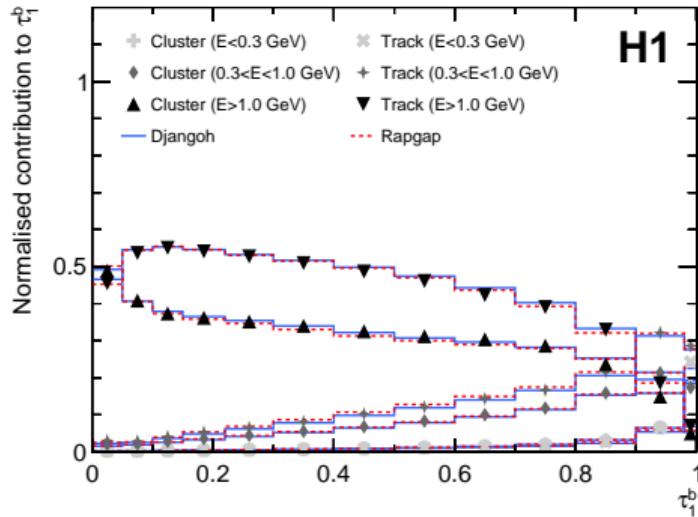

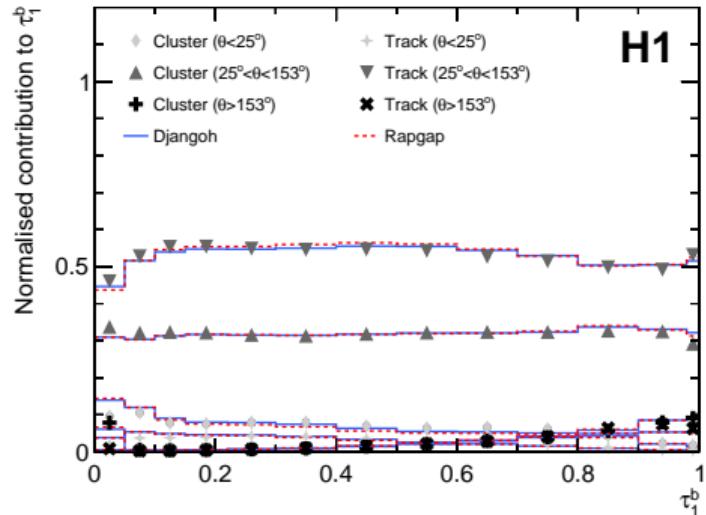

- DIS 1-jet configuration
  - Most HFS particles collinear to scattered parton → Small  $\tau_1^b$
- 1-jettiness defined for every DIS event  
 → All particles can contribute, no jet clustering!

- Dijet event
- More and larger contributions to the sum over the HFS → Large  $\tau_1^b$

# DIS thrust - a $4\pi$ observable

- All particle candidates in all DIS events contribute  $\left(\tau_1^b = 1 - \frac{2}{Q} \sum_{i \in \mathcal{H}_C} P_{z,i}^{Breit}\right)$
- Normalised contribution to  $\tau_1^b$  for different ranges in polar angle  $\vartheta$  and energy

- Mainly tracks and clusters in the central part of the detector contribute ( $25^\circ < \vartheta < 153^\circ$ )
- Mainly particles with high energy contribute ( $E > 1 \text{ GeV}$ )
  - ⇒ Well measured particles dominate in  $\tau_1^b$

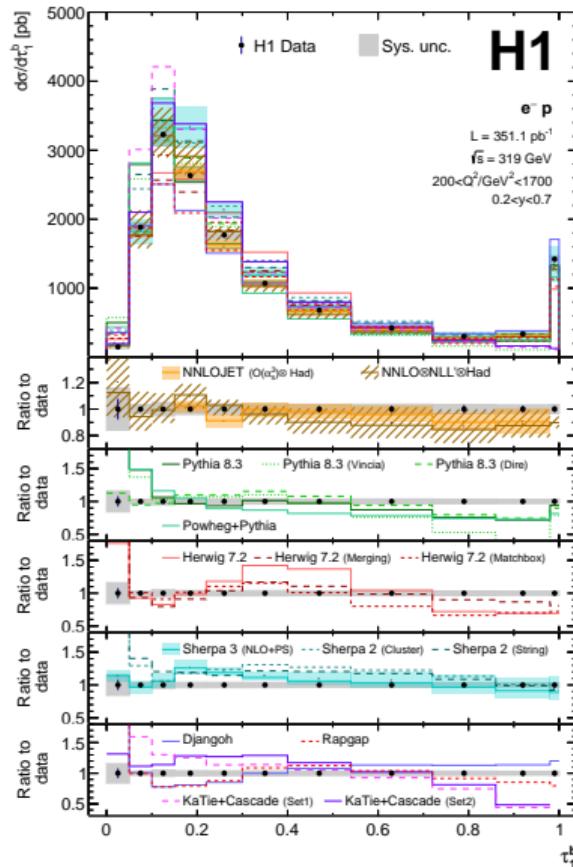

# Single differential cross section

## 1-jettiness cross section

- Data unfolded using TUnfold
- Correct for QED radiation and electro-weak effects
- Resulting cross section reported for  $e^- p$  and  $e^+ p$  collisions

## Comparison with MC models

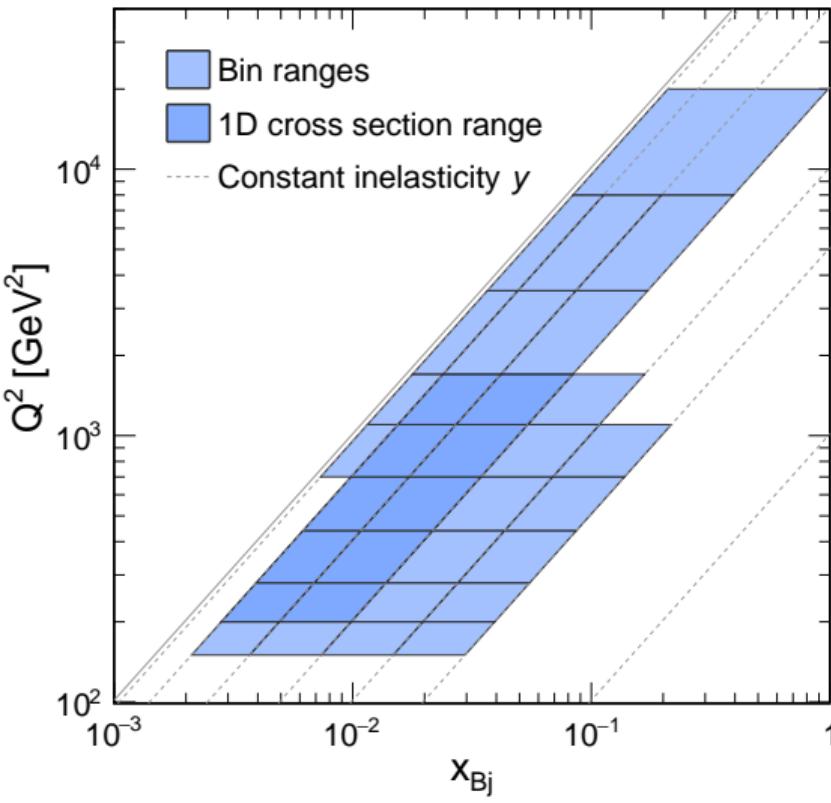

- Compare data to 15 different models
- $\delta$ -distribution at  $\tau_1^b = 1$ 
  - Events with empty current hemisphere
  - Dedicated talk by [Zhiqing](#)
- Cross sections are measured at high precision
  - None of the MC models works perfectly, now have precision data for tuning
  - Exact QCD predictions have sizeable scale uncertainties and large hadronization corrections

**Large cross section and sizeable data**  
→ Triple-diff. cross sections as a function  
of  $Q^2, y, \tau_1^b$

## Triple differential measurement

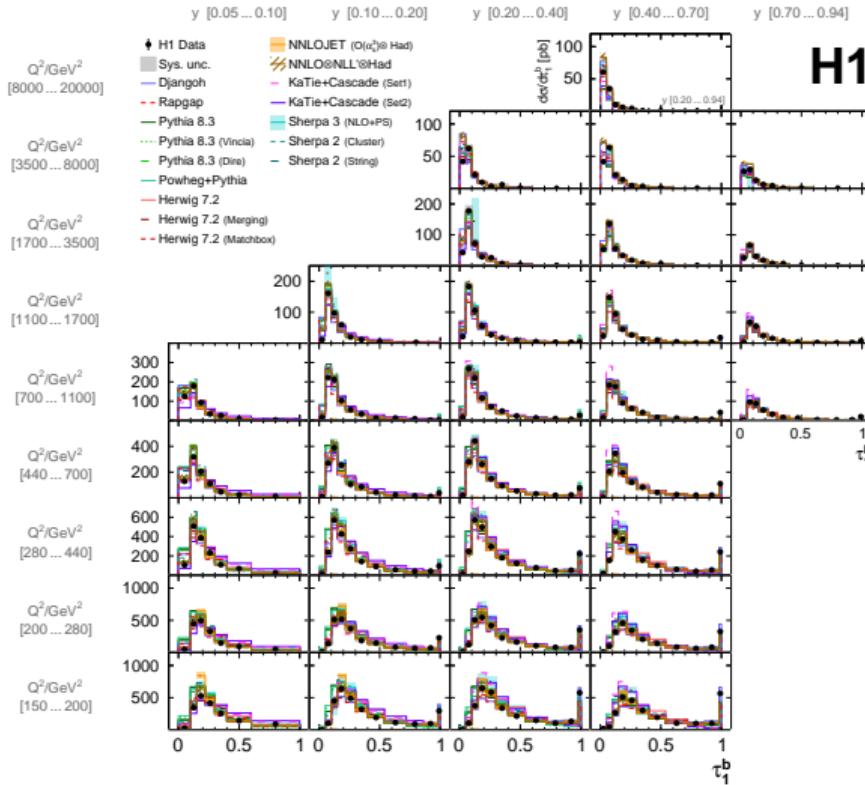

- Investigate change in shape of the distribution
- Integral over the  $\tau_1^b$  distribution results in inclusive DIS cross section

# Triple differential cross sections

## 3D cross sections

- increasing  $Q^2$ 
  - Peak moves to lower  $\tau$
  - Tail region lowers
- Increasing  $y$ 
  - $\tau = 1$  becomes enhanced
- Reasonable description by various models
  - Study ratio to data for better comparison

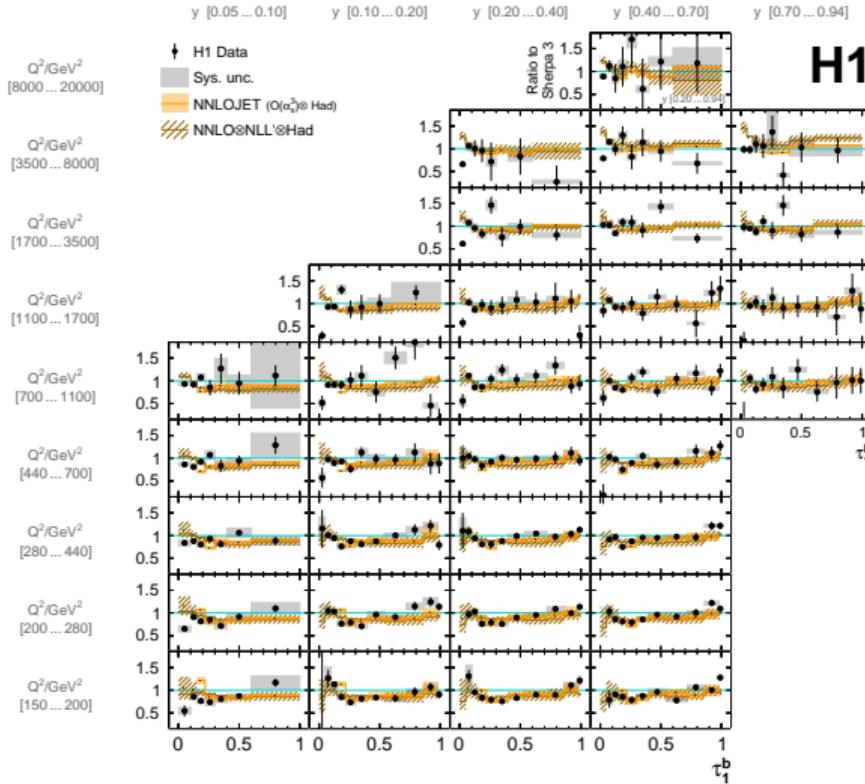

## Uncertainties

- Stat. uncertainties of a few to  $O(10\%)$
- Syst. uncertainties are in the range of 5-10%

## MC comparison

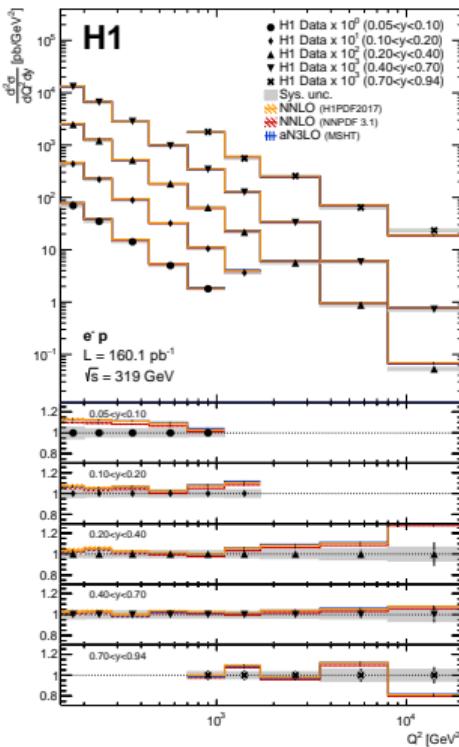

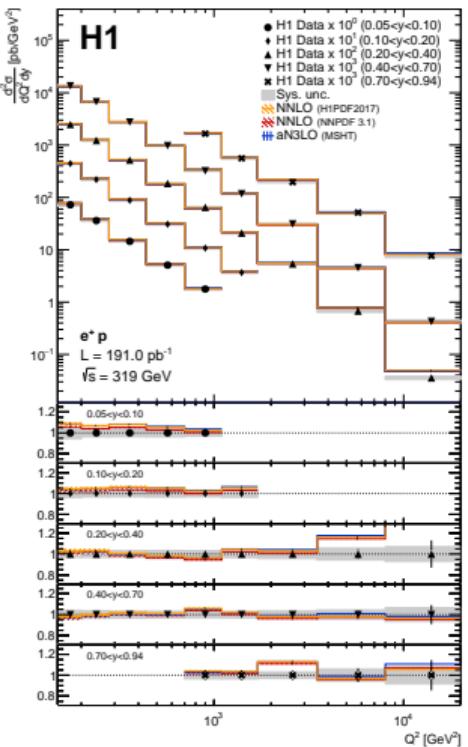

- Ratio to Sherpa 3
- Fixed order calculations provide satisfactory description in region of validity
- Comparison to other MC predictions included in backup

# Double differential cross section

Integrate over  $\tau_1^b$  distribution  
→ Inclusive DIS cross section

- Cross sections for  $e^- p$  and  $e^+ p$  collisions
- Compare the data to fixed order calculations at NNLO and approximate N3LO accuracy  
→ Excellent agreement between data and predictions
- Cross check validates  $\tau_1^b$  measurement

## A first measurement of the 1-jettiness event shape observable in NC DIS was presented

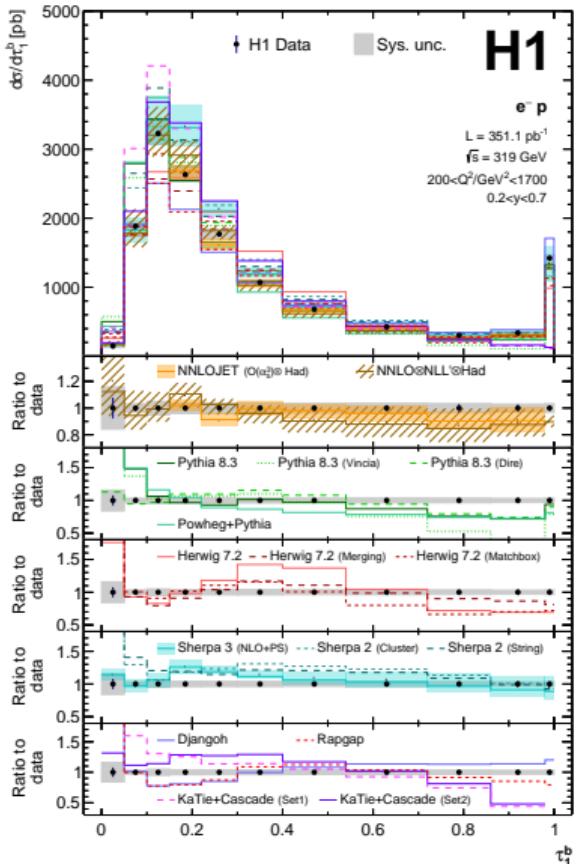

- Defined for every NC DIS event
- Every particle candidate can contribute

## Cross section measurement

- Presented single differential cross sections and in bins of  $y$  and  $Q^2$
- Reasonable description of the data by multiple models
- Integrating over  $\tau_1^b$  results in DIS cross section

Full publication available at [arXiv:2403.10109v1](https://arxiv.org/abs/2403.10109v1)

More H1 event shape results in Henry's talk

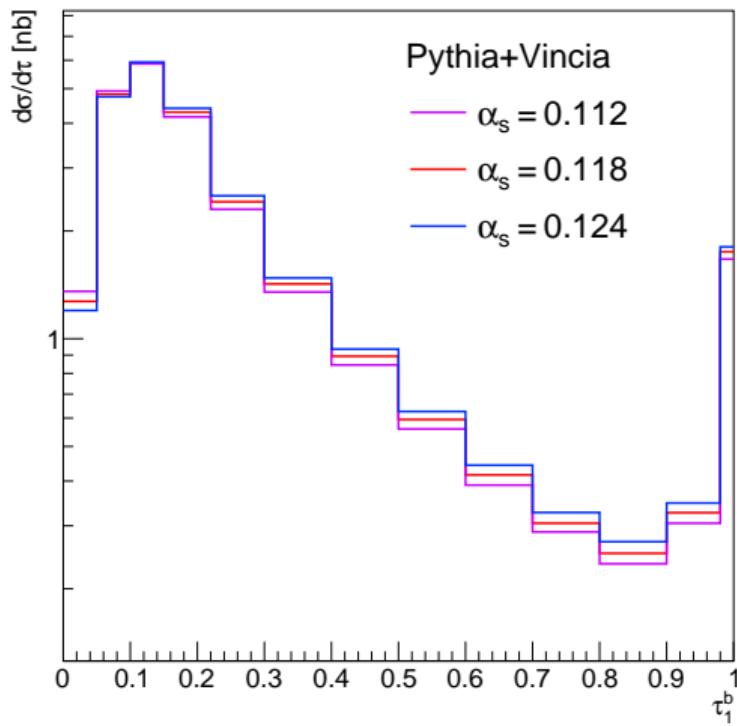

# Backup

## Sensitivity of $\tau_1^b$ to $\alpha_s$

- Plot shows Pythia 8.3 + Vincia prediction for  $\tau_1^b$  on particle level
  - High sensitivity in tail region
  - No sensitivity in peak region (Born level kinematics)

Pythia+Vincia  $\alpha_s$  variations ( $\pm 5\%$ )

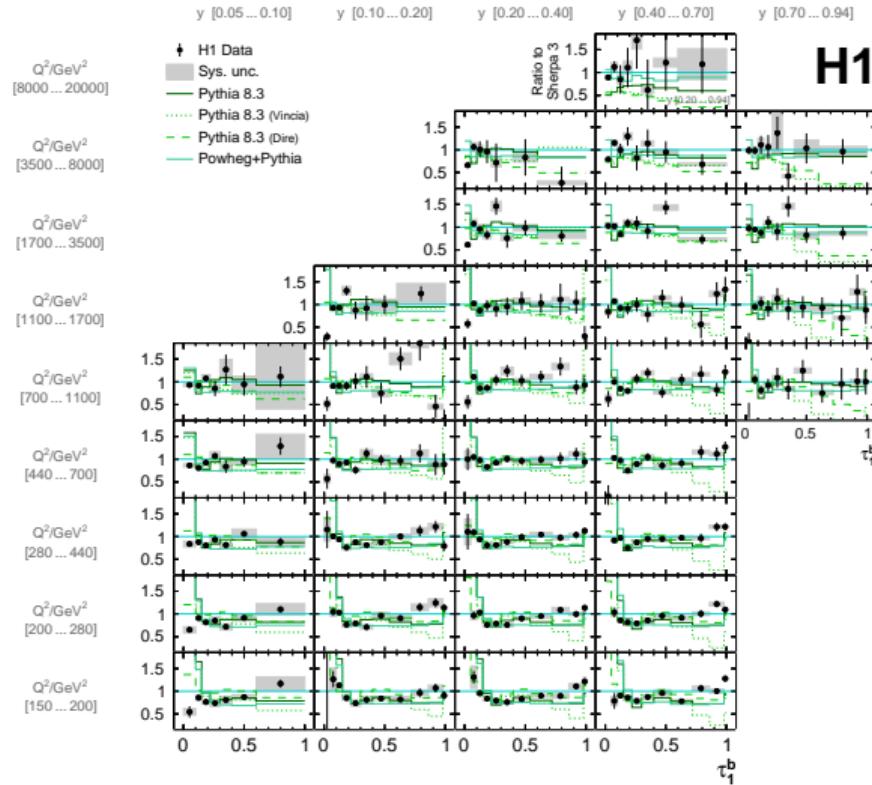

# Triple differential cross sections

## Comparison of data to

- Pythia 8.3
- Pythia 8.3 + Vincia Parton Shower
- Pythia 8.3 + Dire Parton Shower
- Powheg + Pythia

## Ratio to Sherpa 3

- First bin overestimated by MC models
- Good agreement in peak region
- Smaller dependence on PS model at higher  $\tau_1^b$

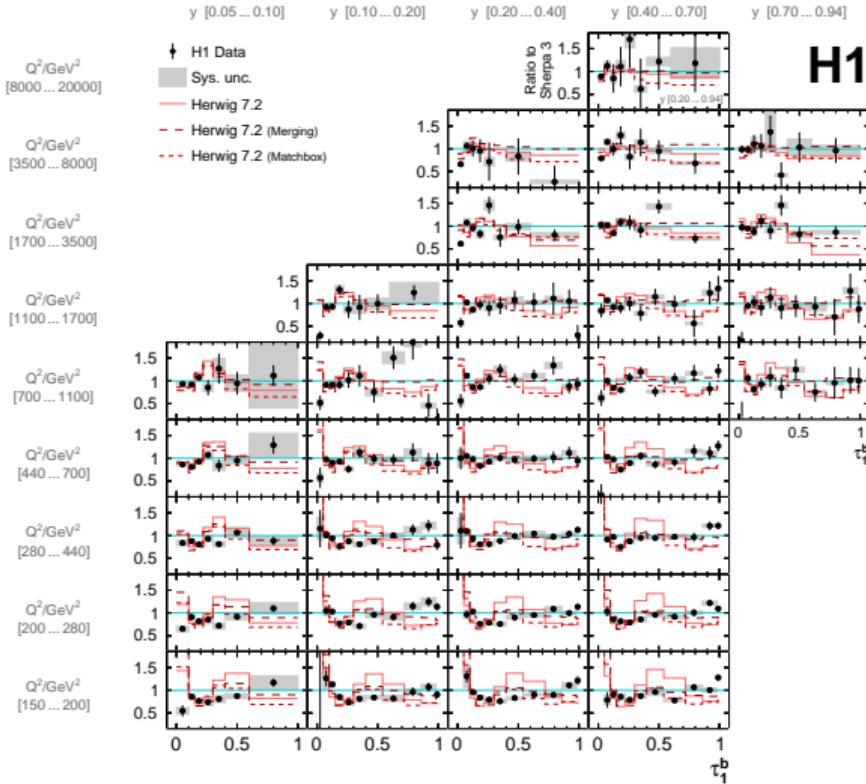

# Triple differential cross sections

## Comparison of data to

- Herwig 7.2
- Herwig 7.2 Merging
- Herwig 7.2 Matchbox

## Ratio to Sherpa 3

- Overestimates data at medium  $\tau_1^b$  and small  $Q^2$

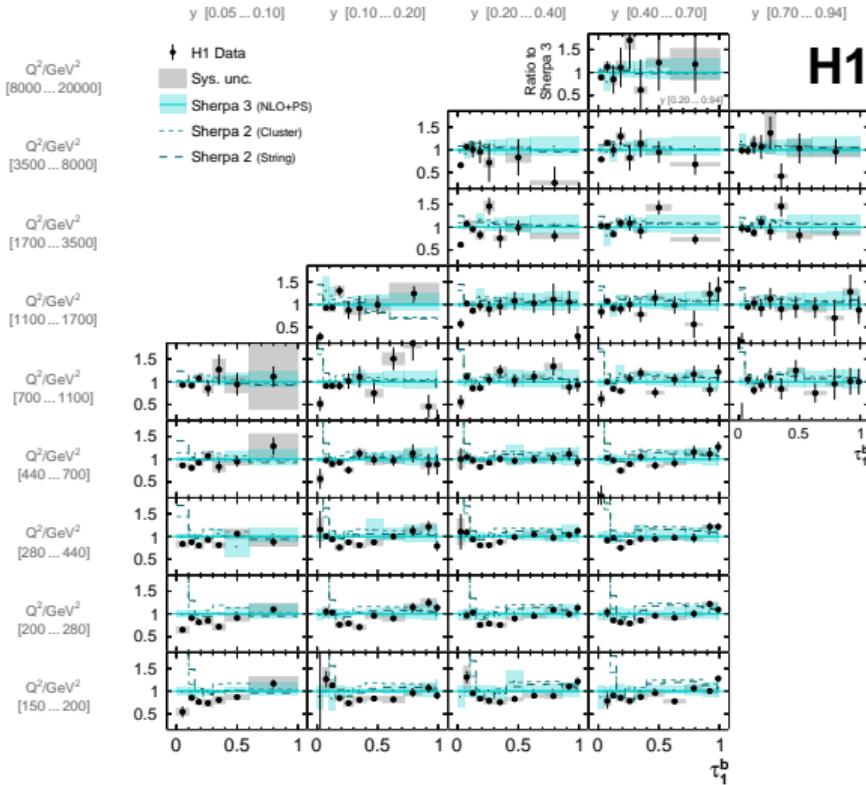

# Triple differential cross sections

## Comparison of data to

- Sherpa 3
- Sherpa 2 (Cluster)
- Sherpa 2 (String)

## Ratio to Sherpa 3

- Best description by Sherpa 3
- Effect of different hadronization model is small

# Triple differential cross sections

## Comparison of data to

- Djangoh
- Rapgap
- KaTie+Cascade (Set 1)
- KaTie+Cascade (Set 2)

## Ratio to Sherpa 3

- Reasonable description of the data by Rapgap and Djangoh
- Good description of data at low  $\tau_1^b$  by KaTie+Cascade but fail to describe tail region
